Abstract

This study demonstrates a novel approach for the synthesis of silver nanoparticles (AgNPs) against human liver cancer cell line (HepG2) using prodigiosin pigment isolated from *Serratia marcescens*. It further investigates the influence of various parameters such as initial pH, temperature, silver nitrate (AgNO₃) concentration, and prodigiosin concentration on stability and optical properties of synthesized prodigiosin AgNPs. Highly stable, spherical prodigiosin-conjugated AgNPs were synthesized with a mean diameter of 9.98 nm using a rapid one-step method. The cytotoxic activity investigated in the present study indicated that prodigiosin and prodigiosin-conjugated AgNPs possessed a strong cytotoxic potency against human liver cancer. The *in silico* molecular docking results of prodigiosin and prodigiosin-conjugated AgNPs are congruent with the *in vitro* studies and these AgNPs can be considered as good inhibitors of mitogen-activated protein kinase 1 (MEK kinases). The study opened the possibility of using prodigiosin-conjugated AgNPs to increase the efficiency of liver cancer treatment.

Key words: silver nanoparticles, cytotoxic activity, *Serratia marcescens*, *in silico*, prodigiosin

Introduction

Biological metallic synthesis of nanoparticles is a green ecofriendly technology since it neither involves harmful chemicals nor high temperatures (Sastry et al., 2003; Bhattacharya and Gupta, 2005; Durán et al., 2007; Gade et al., 2008; Mukherjee et al., 2008; Fayaz et al., 2010; Thakkar et al., 2010; Narayanan and Sakthivel, 2011; Rubilar et al., 2013). A wide spectrum of biological, chemical, and physical applications of biosynthesized nanoparticles covers, among others, drug delivery, cancer and gene therapy, DNA analysis, antiviral, antibacterial, and antifungal agents, diagnostic devices, anti-coagulant, thrombolytic, and nanocatalysis (Gong et al., 2007; Li et al., 2011; Manikprabhu and Lingappa, 2014; Azeez et al., 2016; Ojo et al., 2016; Lateef et al., 2016a, 2016b, 2017). Nanoparticles of desired shapes and sizes can be obtained by controlling the synthesis conditions.

In the same regard, temperature and pH are reported to control AgNPs size in the supernatant of *E. coli* (Gurunathan et al., 2009a, 2009b; Ganesh Babu and Gunasekaran, 2009, 2013).

The most significant goals of cancer therapy research include the recognition of novel targets and the discovery of more specific chemotherapeutic agents. Prodigiosin is a family of natural red pigments produced by various bacteria including Gram-negative rods such as *Serratia marcescens* (Bunting, 1940; Weiss, 1949; Hubbard and Rimington, 1950; Castro et al., 1959; Williams et al., 1956; Rapoport and Holden, 1962; Khanafari et al., 2006), *Pseudomonas magneso rubra* (Gerber, 1975), *Vibrio psychroerythrous* (D'Aoust and Gerber, 1974), *Serratia rubidaea* (Gargallo-Viola, 1989), *Vibrio gazogenes* (Allen et al., 1983), *Alteromonas rubra* (Gerber and Gauthier, 1979), *Rugamonas rubr* (Maurice, 2002),

* Corresponding author: Botany and Microbiology Department, Faculty of Science, Helwan University, 11795, Cairo, Egypt; e-mail: professor.ahmed85@gmail.com

Hahella chejuensis (Huh et al., 2007; Kim et al., 2008); and Gram-positive actinomycetes such as *Streptovorticillium rubrreticuli* (Gerber and Stahly, 1975), *Streptomyces griseoviridis* (Kawasaki et al., 2008), *Streptomyces longisporus Ruber* (Wasserman et al., 1969), and *Streptomyces coelicolor A3(2)* (Harris et al., 2004). Prodigiosin, a bacterial metabolite, is a tripyrrole nitrogen ring pigment synthesized by *Serratia marcescens* (Williams, 1973; Kavitha et al., 2010). This red pigment is a promising drug owing to its antimicrobial and immunomodulatory activities (Lee et al., 1995; Da Silva Melo et al., 2000). It is produced by *Serratia marcescens* following a bifurcated biosynthesis pathway in which the separately obtained mono and bipyrrole precursors are coupled to form the linear tripyrrole red pigment (Boger and Patel, 1988) during the stationary phase of bacterial growth (Rokem and Weitzman, 1987). *Serratia* pigment genes clusters contain 14 genes common to *Serratia* which are named from *pigA* to *pigN* (Cerdeño et al., 2001; Harris et al., 2004). The cytotoxic properties of prodigiosin were recognized for several decades. Fullan and coworkers (1977) observed the antitumor activity of prodigiosin in mice. Some cancer chemotherapeutic agents act primarily by inflicting apoptotic death in susceptible cancer cells. Each of these chemotherapeutic agents interacts with a specific target, causing susceptible cancer cells to undergo apoptosis (Hannun, 1997). Prodigiosin quickly and powerfully triggers the cell death in hematopoietic cancer cells, human breast carcinoma cell lines (Pan et al., 2012), gastric cancer cell line HGT-1 (Díaz-Ruiz et al., 2001), human colon cancer cells (Montaner and Perez-Tomas, 2001), and lung cancer cell lines (Llagostera et al., 2005). However, nonmalignant cells showed no marked toxicity (Montaner et al., 2000). Prodigiosin is also shown to possess cytotoxic activity against human tumor-derived cell lines (Pandey et al., 2007; Venil, 2009). Suppression of cell proliferation, as well as initiation of cell death, was recognized in these cell lineages. *In vitro* anticancer activity was also described for different analogs and synthetic indole derivatives of prodigiosin (Pandey et al., 2007). Prodigiosin pigment showed antiproliferative and cytotoxic effects in both cultured tumor cell lines and human primary cancer cells (Campàs et al., 2003).

Liver cancer (hepatocellular carcinoma) is the third most frequent cause of death in malignant neoplastic disease and the estimated percentage of death rate is

increasing in most of the developing countries (Siegel et al., 2013; Ashokkumar et al. 2014). In addition, prodigiosin also exhibited cytotoxic activity to doxorubicin (DOX)-resistant human small cell lung carcinoma cells and overexpressing multidrug resistance-related proteins (Llagostera et al., 2005; Venil, 2009). Cycloprodigiosin hydrochloride displayed a high cytotoxic potency against liver cancer cells, without any toxicity to normal cells, and its cost-effectiveness as a hepatocellular carcinoma drug increased the possibility of its therapeutic use (Yamamoto et al., 1999). The aim of this study was to investigate the possible use of prodigiosin pigment as a stabilizing, reducing, and coating agent for AgNPs synthesis, and to evaluate the cytotoxic effect of as-prepared AgNPs in human liver cancer cells (HepG2). It was demonstrated that the biological pigments, including those synthesized by bacteria, can be used for green synthesis of nanoparticles (Apte et al., 2013; Nair et al., 2013; Adelere and Lateef, 2016; Manikprabhu and Lingappa, 2013a, 2013b, 2014).

Materials and methods

Bacterial isolate

Serratia marcescens WSE was isolated from irrigation water collected from Almaryoteia Canal, Giza Governorate, Egypt. The bacterial culture was maintained on nutrient agar (NA) slant at 28 °C for 24 h prior to storage at 4 °C for subsequent studies. The stored bacterial culture was subcultured monthly to maintain bacterial viability.

Preparation, extraction, purification, and quantification of prodigiosin

Prodigiosin extraction was carried out as described by Pradeep and coworkers (2013). A loop full of *Serratia marcescens* WSE grown on NA plates was inoculated into a 250 ml flask with 50 ml nutrient broth (NB) containing 5.0 g/l peptone and 3.0 g/l beef extract supplemented with 5 mg/ml L-tyrosine and was incubated in a shaking incubator (VS-8480 SRN, Korea) at 3 rcf and 28 °C for 24 h. A 10 ml portion of the culture broth was centrifuged (Centurion Scientific K3 Series Centrifuges) at 4032 rcf and 4 °C for 15 min. Prodigiosin was extracted from the cell pellet as described by Pradeep and coworkers (2013). The cell pellet was resuspended in 10 ml of 95% ethanol, and the extract was further processed by sonication using an ultrasonic homogenizer

(BioLogics Ultrasonic Homogenizer Model 150VT; BioLogics Inc, Manassas, VA, USA). Sonication time and pulsar rate were adjusted at 40% pulsed power and 30% pulsar rate for 3 min until the solution became colorless. The mixture was vortexed and the suspension was centrifuged at 4032 rcf and 4 °C for 10 min (Slater et al. 2003). It was then filter sterilized through a 0.45- μ m Whatman® Optitran® reinforced nitrocellulose membrane filter. The extracted pigment was transferred into a round-bottom flask (Schott Duran, Germany), and then evaporated using vacuum rotary evaporator (Heidolph WB 2000, Germany) at 50 °C, the dry weight was then determined according to the protocol given by Garg and coworkers (2013). The extracted prodigiosin was applied to a thin layer chromatography (TLC) plate using a mixture of chloroform and methanol (9:1) as the solvent system for further purification (Casullo de Araújo et al., 2010). Prodigiosin was also passed through silica gel column chromatography (2.5 × 30 cm; Kieselgel 60; Merck, Darmstadt, Germany, mesh size: 60-80) (Montaner and Pérez-Tomás, 2002) to separate the colorless impurities. The dried sample was dissolved in 5 ml of *n*-hexane and loaded onto a silica gel column with an *n*-hexane and ethyl acetate solvent system (2:0; v/v to 0:2; v/v) at 1 ml/min flow rate. Chromatographic separation through high-performance liquid chromatography (HPLC) was carried out using a C18 column for reverse phase chromatography (Eclipse plus C18, 4.6 × 100 mm), with 0.8 ml/min flow rate and 10 μ l injection volume. Mobile phase was acetonitrile/HPLC water (60:40, v/v). The amount of pigment produced in bacterial cells and supernatant was determined by addition of 100 μ l of 0.1N HCl to 10 ml of the supernatant and also by ethanolic extraction (Faraag et al., 2017). The total pigment was estimated by Spekwin32 optical spectroscopy software. Prodigiosin concentration was calculated by measuring the absorbance at 535 nm (Chen et al., 2006) using an extinction coefficient as 51.3×10^3 ($l \text{ mol}^{-1} \text{ cm}^{-1}$) (Williams et al., 1961, 1971). Concentration of the total pigment yield (mol/l) was calculated using Spekwin32 version 1.71.6 (Menges, 2011).

Synthesis of AgNPs using prodigiosin

Prodigiosin was diluted with deionized water to a pigment final concentration of 4 μ g/ml, followed by the addition of the aqueous AgNO₃ solution to 1 mM final concentration. Finally, the volume was adjusted to 10 ml

with deionized water (dd). The reaction was carried out at 20 °C for 24 h.

Factors controlling the size and shape of synthesized AgNPs

Initial pH

AgNPs were synthesized at a pH value adjusted over the range between 6 and 13. As previously mentioned, the synthesis was carried out using prodigiosin pigment with 1mM AgNO₃. The pH value was adjusted with 0.1 N HNO₃ and 0.1 N NaOH.

Temperature

The effect of temperature on AgNPs synthesis was observed over a range of temperatures from 10 to 100 °C. Synthesis of AgNPs at optimum pH was determined in a previous step.

Silver nitrate concentration

Various concentrations of AgNO₃, ranging from 1 to 10 mM in test tubes containing 4 μ g/ml prodigiosin, were used to determine the effect of AgNO₃ concentration on the synthesis of AgNPs. The volumes were adjusted to 10 ml with dd H₂O. The reactions were incubated at 30 °C and pH 13 for 24 h. Formation of AgNPs was confirmed by UV-visible spectrophotometry.

Prodigiosin concentration

The effect of different prodigiosin concentrations (1, 2, 3, 4, 5, 10, 100, 200, 300, and 500 μ g/ml) on the synthesis of Ag nanoparticles was examined using AgNO₃ at its optimum concentration and pH value determined at previous experimental stages, incubated at 30 °C for 24 h.

Time evolutions for synthesis of AgNPs

The time evolutions for the synthesis of AgNPs were studied at regular intervals of 20 min for 2 h, and then after 18 h, as previously mentioned. The visualized color change to dark brown was observed in the reaction mixture and confirmed using UV-VIS spectrophotometry along with the other methods of characterization.

Characterization of the synthesized AgNPs – UV-VIS spectral analysis

AgNPs were characterized according to the protocol by El-Batal and coworkers (2013) as follows: UV-VIS spectroscopy analysis was carried out using a JASCO V-630 UV-VIS spectrophotometer (Pgeneral, China), where the maximum absorption spectra were analyzed

over a range of 200-800 nm, at a resolution of 1 nm, and a scan speed of 400 nm/min (El-Batal et al., 2013). Base-line correction of the spectrophotometer was carried out using a blank reference. The UV-VIS absorption spectra of all the samples were recorded and numerical data were plotted and analyzed by the Spekwin32 version 1.71.6.1 (Ramezani et al., 2008; Menges, 2011).

Dynamic light scattering

Average particle size and size distribution of dissolved nanoparticles were analyzed by dynamic light scattering (DLS) (PSS-NICOMP 380-ZLS particle sizing system St. Barbara, California, USA). The samples were diluted 10 times with deionized water before measurements and 250 μ l of suspensions were transferred to disposable low volume cuvettes. After equilibration at 25 °C for 2 min, 5 measurements of each sample were taken using 12 runs of 10s each (Poole and Owens, 2003; Kohler and Fritzsche, 2004).

Transmission electron microscopy analysis

Transmission electron microscopy (TEM) studies were performed using (JEOL Electron Microscopy JEM-100 CX, FEI, America) electron microscope operating at an accelerating voltage of 200 KV. For TEM measurements, a drop of the resulting solution was placed on a copper grid covered with amorphous carbon. After allowing the film to stand for 2 min, the extra solution was removed with blotting paper and the grid was allowed to air dry before the measurement (Poole and Owens, 2003).

Fourier transform infrared spectroscopy spectral analysis

Fourier transform infrared (FTIR) measurements were carried out to obtain information about the stabilizing chemical groups present around AgNPs and to understand the transformation of functional groups due to the reduction process. The resulting solutions were diluted with potassium bromide (KBr) in a 1:100 ratio, and after drying at room temperature they were compressed to form disks to be analyzed further by FTIR spectra (4000-400 cm^{-1}), at JASCO FT-IR-3600 (Bruker, Germany), by employing the KBr pellet technique at a 4 cm^{-1} resolution (Anderson et al., 2004; Hesse et al., 2008).

X-ray diffraction pattern of AgNPs

The AgNPs were investigated by X-ray diffraction (XRD) technique (6000, Shimadzu, Japan) using copper

potassium alpha ($\text{CuK}\alpha$) radiations (Kohler and Fritzsche, 2004). AgNPs solution was placed on a glass slide to form a film and was dried at room temperature. In the next step a scan was performed using XRD operating with a Cu anode at 40.0 (kV) voltage and 30.0 mA current, in the 2θ range value, between 20° and 100°, with a speed of 2°/min and continuous scan mode (Duane et al., 1997). Each diffraction peak was corrected for background scattering and was stripped of $\text{K}\alpha_2$ portions of the diffracted intensity.

Cytotoxicity assay for anticancer-drug screening

AgNPs were dried using silica gel as a desiccant in a desiccation chamber. Cytotoxicity assay for anticancer-drug screening was carried out with sulforodamine B (SRB) assay according to a procedure by Skehan and coworkers (1990). Cells were seeded in 96 well micro-liter plates at 1000-2000 cells/well concentration in 100 μ l. After 24 h, cells were incubated for 72 h with various concentrations of drugs (10 mM stocks of prodigiosin and nanosilver: 10 mM stock DOX), and then 10-fold serial dilutions (0, 0.01, 0.1, 1, 10, and 100 unit) were prepared. The plates were incubated for 48h, then the medium was discarded and cold trichloroacetic acid was added per 150 μ l well to 10% final concentration and incubated for 1 h at 4 °C for cell fixation. The cells were washed three times with sterile distilled water (TCA reduces SRB protein binding). The wells were then stained for 10-30 min at room temperature with 0.4% SRB dissolved in 1% acetic acid (70 μ l/well) and kept in the dark. They were washed with 1% acetic acid to remove the unbound dye until the washing solution was colorless. The plates were air dried (24 h). The dye was solubilized with 150 μ l/well 10 mM tris-base (pH 7.4) for 5 min on a shaker, at 287 rcf. The optical density (OD) of each well was measured spectrophotometrically at 545 or 540 nm with an ELISA microplate reader (Skehan et al., 1990). The IC_{50} values were calculated using sigmoidal concentration response curve fitting models (Sigmaplot software).

In silico docking study of cytotoxic activity

The docking study was carried out on an Intel Dual-Core (1.8 GHz) Windows PC with Molegro Virtual Docker (MVD) 2013.6.0.0 (Thomsen and Christensen 2006). The two-dimensional structure of prodigiosin conjugated with silver was converted into a three-dimensional for-

mat for docking purposes using ChemOffice 2010 (CambridgeSoft Corporation). Prodigiosin and DOX ligands were obtained from PubChem Bioassay. Crystallographic structure of MEK1 kinase (Mitogen-activated protein kinase kinase) was obtained from the protein data bank [(4LMN-PDB) Research Collaboratory for Structural Bioinformatics (RCSB) (<http://www.rcsb.org/pdb>)]. The protein originated from *Homo sapiens*. Its resolution was 2.80 Å with 0.2884 *R*-value (Hatzivassiliou et al., 2013). The binding sites of the protein were determined using MVD and 5 cavities having 469.504 Å³ total volume and 1111.04 Å² surface area were predicted. The binding site was set inside a restriction sphere of 15 Å radius using MVD. All other software parameters for docking were set to the default values. The parameters were as follow: The “MolDock SE” searching algorithm was used with the number of runs set to 10 using a maximum of 1500 iterations and a total population size of 50. The energy threshold used for the minimized final orientation was 100. The Simplex evaluation with 300 maximum steps of neighbor distance factor 1 was completed. The chosen cavity was further refined using side-chain minimization by selecting the add-visible option at a maximum (10 000) of steps per residue and a maximum (10 000) of global steps. The setup for side-chain flexibility by selection of the add-visible option, setting for the selected flexible side chain during the docking option, and other parameters were all kept in default. All docking calculations were carried out using the grid-based MolDock score (GRID) function with 0.30 Å grid resolution.

Results

Synthesis of AgNPs using prodigiosin pigments – effect of initial pH value on the synthesis of AgNPs

The effect of initial pH value of prodigiosin aqueous solution is an important parameter in the synthesis of AgNPs. That parameter was studied at different pH values ranging from 6 to 13. Figure 1 shows that the absorption spectra of AgNPs with surface plasmon resonance (SPR) band blue-shifted due to an increase in the pH value from 9 to 13 and showed a maximum absorbance at pH 13. Interestingly, at pH values ranging from 6 to 8, the absorption peaks could not be observed indicating that AgNPs synthesis was not initiated in a solution having pH value below 9. As the pH value increased

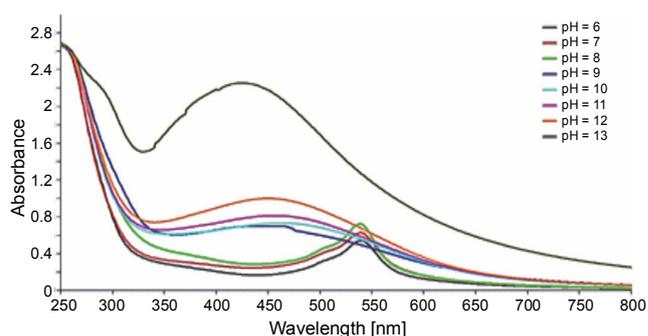

Fig. 1. UV–VIS spectra of AgNPs synthesized by prodigiosin at pH value ranging from 6 to 13

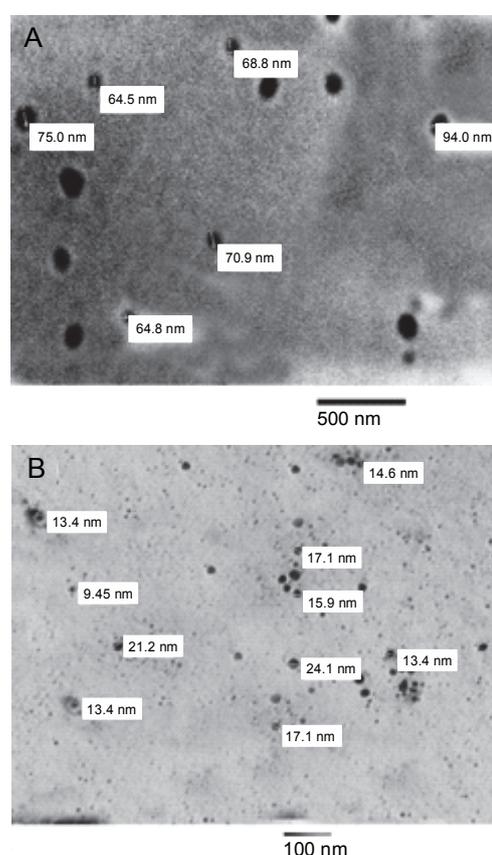

Fig. 2. TEM micrographs of AgNPs synthesized at A) pH 9 and B) pH 13

the SPRs blue-shifted and absorbance intensity increased; however, the size of AgNPs reduced. TEM images of synthesized AgNPs by prodigiosin showed spherical nanoparticles with a mean size of 11.26 nm at pH 13, and a mean size of 73.0 nm at pH 9 (Fig. 2).

Effect of temperature on the synthesis of AgNPs

The effect of temperature on the formation of AgNPs was also investigated. All the reaction temperatures sho-

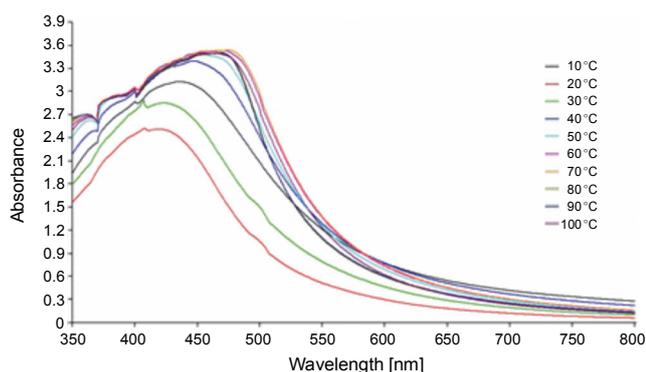

Fig. 3. UV-VIS spectra of AgNPs synthesized by prodigiosin at different temperatures

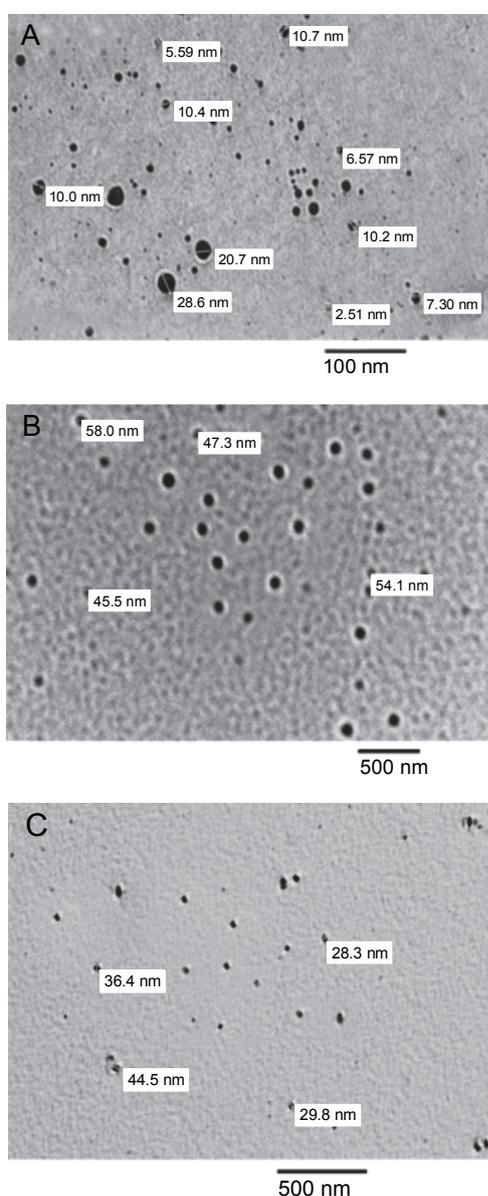

Fig. 4. TEM micrographs of AgNPs synthesized using 4 µg/ml prodigiosin at pH 13 and 1 mM AgNO₃ after 24 h at different temperatures A) 30°C, B) 70°C and C) 100°C

wed SPR band intensities. A red shift of the SPR band was observed because of the increase in the reaction temperature from 20°C to 70°C. However, the increase from 80°C to 100°C resulted in a decrease in the wavelength of the absorbance peaks for the synthesized AgNPs with a small blue shift (Fig. 3). The peaks red-shifted as the size of AgNPs increased. As shown in TEM images, these AgNPs were spherical with a mean diameter of 11.25, 51.22, and 34.75 nm when synthesized at 30°C, 70°C, and 100°C, respectively (Fig. 4).

Effect of AgNO₃ concentration on the synthesis of AgNPs

The sizes of AgNPs can be controlled by varying the concentration of AgNO₃ used for the reduction reaction. The synthesis of smaller AgNPs is accompanied by visible color changes of silver metal (Katok et al. 2009). A red shift of the SPR was observed because of the gradual increase in the concentration of AgNO₃ (from 1 to 10 mM, Fig. 5). TEM images show spherical nanoparticles with a mean diameter of 14.11 nm at 1 mM AgNO₃ concentration. However, anisotropy of irregular ellipsoids or rod-shaped AgNPs were formed at 4 mM AgNO₃, with a mean length of 108 nm and width of 23.76 nm (Fig. 6).

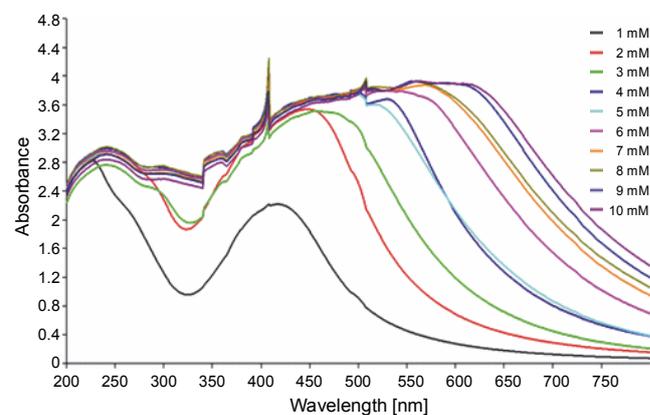

Fig. 5. UV-VIS spectra of AgNPs synthesized by prodigiosin at different AgNO₃ concentration ranging from 1 mM to 10 mM

The effect of different concentrations of prodigiosin on the synthesis of AgNPs

UV-VIS spectra of AgNPs synthesized using prodigiosin pigment at different concentrations are shown in Figure 7. SPR peak was not observed at 2 µg/ml; however, the addition of 4 µg/ml enhanced the synthesis of AgNPs as indicated by SPR peaks. SPR peak intensities

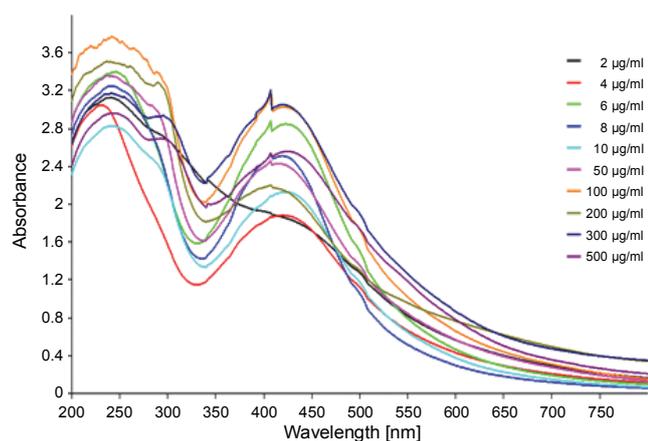

Fig. 7. UV-VIS spectra of AgNPs synthesized using different prodigiosin concentrations and pH 13 at 30°C after 24 h and 1 mM AgNO₃ concentration

increased as the concentration of pigment increased. However, as the concentration increased from 4 µg/ml to 500 µg/ml, the wavelength of absorbance peak for the synthesized AgNPs increased with a small red shift that

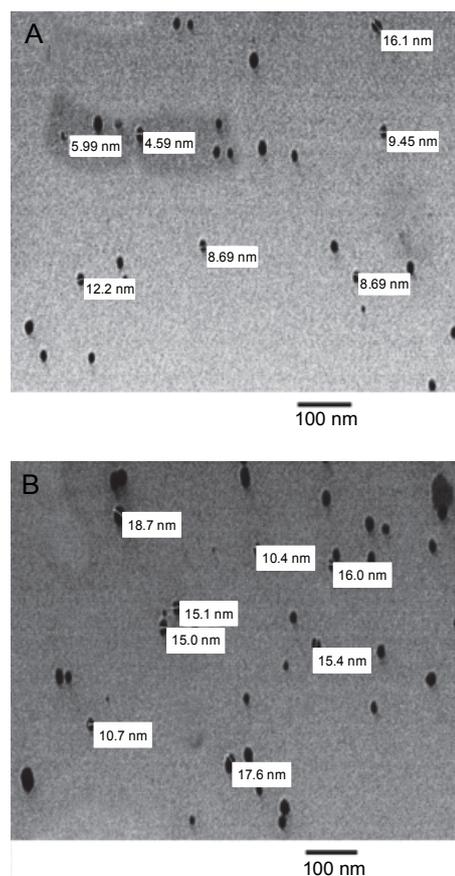

Fig. 8. TEM micrographs of AgNPs synthesized using 1 mM AgNO₃ at pH 13 and A) 4 µg/ml and B) 500 µg/ml prodigiosin

appeared between 420 and 425 nm. TEM images showed spherical nanoparticles with a mean diameter of 9.98 nm and 14.86 nm at 4 µg/ml and 500 µg/ml, respectively (Fig. 8).

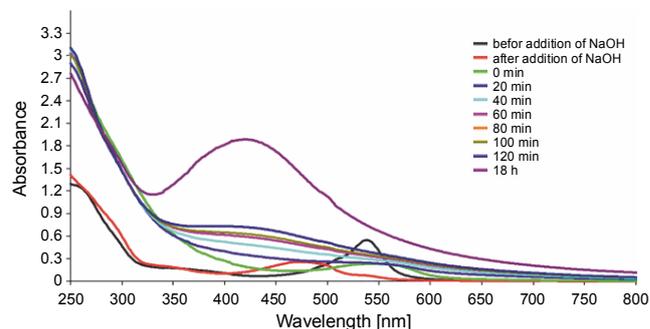

Fig. 9. UV-VIS spectra analysis of synthesized AgNPs after addition of 1 mM AgNO₃ to 500 µg/ml prodigiosin pigment at pH 13 during time intervals

Time evolutions for synthesis of AgNPs

Figure 9 showed no absorption peak after 20 min, however, the absorption band intensity increased with

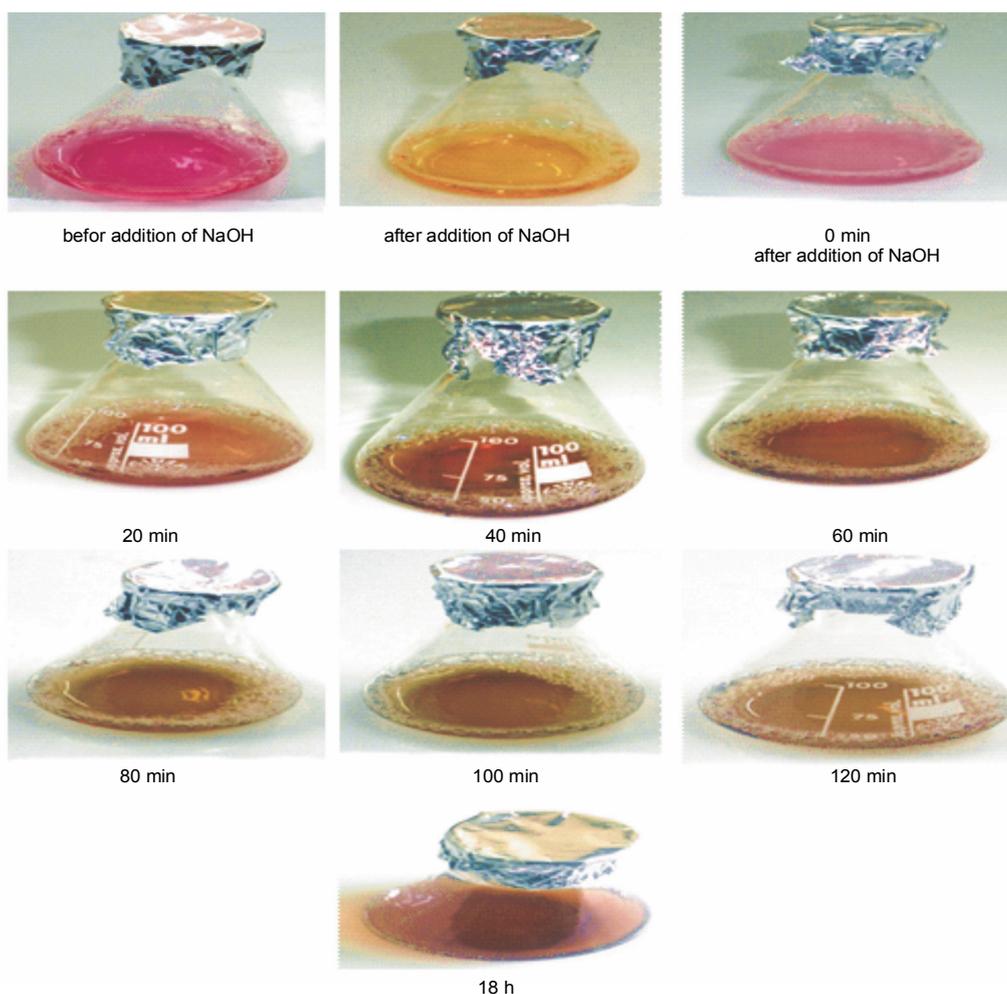

Fig. 10. Formation of AgNPs using prodigiosin during time intervals

time duration due to the continuous formation of AgNPs. A weak absorption peak began to appear at 396 nm after 120 min. An absorption peak of AgNPs at 422 nm after 18 h corresponds to those chemically conjugated with prodigiosin. Meanwhile, the color changed from red to yellow after addition of NaOH and returned to red after addition of AgNO₃. Finally, the color changed to brown after 10 min as an indication of the formation of AgNPs (Fig. 10).

X-ray diffraction pattern of AgNPs

XRD measurements were performed to characterize crystal structures of the AgNPs as showed in Figure 11. Five well-defined characteristic diffraction peaks at 38.2°, 44.1°, 64.72°, 77.4°, and 81.50° (2θ values) corresponded to the reflections from the (111), (200), (220), (311), and (222) planes, respectively, and confirmed the crystalline phase of the AgNPs. Moreover, the

intensity of the (111) diffraction was much stronger than those of the (200), (220), (311), and (222) diffractions.

Reduction mechanism

FTIR measurement was carried out to determine the reduction mechanism and identify potential functional groups responsible for the synthesis and stabilization of prodigiosin-conjugated AgNPs. Figure 12 shows the FTIR spectra of prodigiosin (before bioreduction) and prodigiosin-conjugated AgNPs (after bioreduction). Four bands (at 2815.2 cm⁻¹, 1654.0 cm⁻¹, 1438.0 cm⁻¹, and 1423.0 cm⁻¹) showed significant changes after synthesis of AgNPs. This peak, found only in AgNPs combination, may be due to conjugation of AgNPs with the free sites of methylene groups of prodigiosin pigment in symmetrical stretching at 2815.2 cm⁻¹. Moreover, the peaks at 1654 cm⁻¹ were found only in AgNPs combination due to

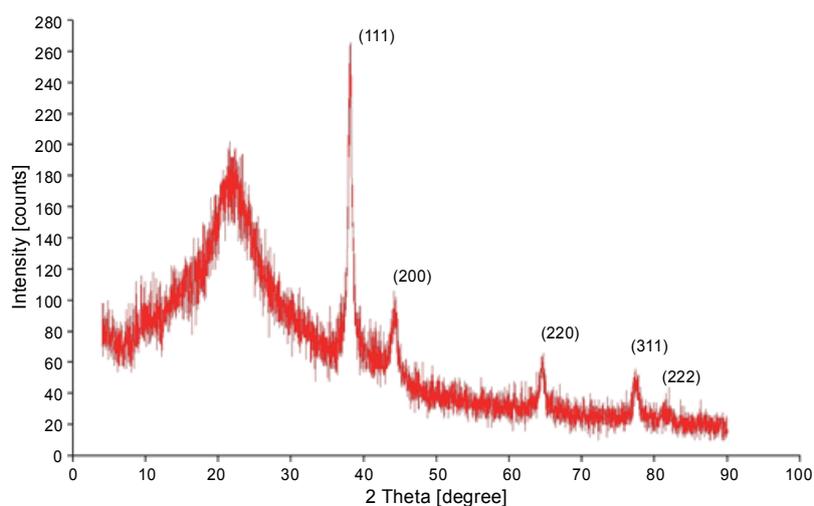

Fig. 11. The XRD pattern of Ag nanoparticles conjugated with prodigiosin, obtained using CuK radiation ($\lambda = 0.154$)

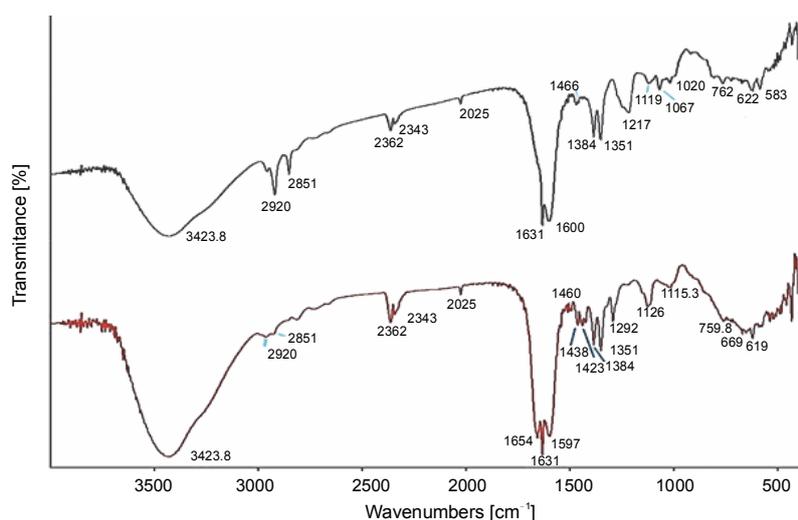

Fig. 12. FTIR spectra of prodigiosin (black line) and prodigiosin-conjugated nanosilver (PG-AgNPs) (red line)

the conjugation of AgNPs to the $-NH$ function groups in prodigiosin. A new peak was also formed at both 1438.0 cm^{-1} and 1423 cm^{-1} due to the formation of new chemical covalent bonds between AgNPs and methyl groups present in prodigiosin, facilitating conjugation between nanometal and methyl groups in the dye.

The solubility of $AgNO_3$ induce the formation of silver oxide in solutions of sufficient alkalinity and the presence of amphoteric properties is mainly a consequence of the equilibrium represented by the following reaction (Johnston et al., 1933).

Figure 13 shows the amphoteric properties of silver oxide in alkaline solutions of the equilibrium reacting with positively charged pyrrole ring of prodigiosin which resulted in the formation of prodigiosin-conjugated AgNPs (PG-AgNPs). The predicted structure was generated using LigandScout 3.2 consisting of overall pharmacophore features: two hydrogen bond donors, two hydrogen bond acceptors, and an aromatic ring (Wolber and Langer, 2005).

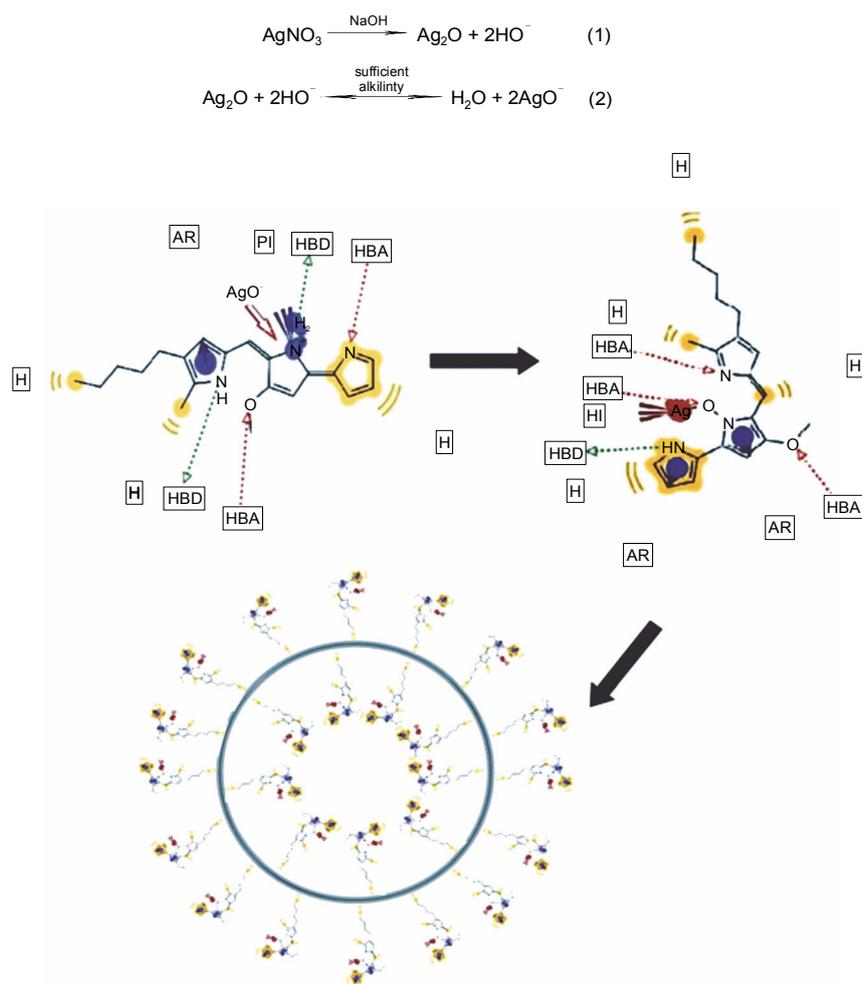

Fig. 13. The mechanism of AgNPs synthesis using prodigiosin (chemical properties and ligand investigation of prodigiosin was performed using LigandScout 3.2)

The cytotoxic effect of prodigiosin and prodigiosin-conjugated AgNPs

PG-AgNPs had a potent anticancer activity against the liver cancer cell forms of HepG2 cell line ($\text{IC}_{50} = 29.8548 \mu\text{g/ml}$) compared to prodigiosin that had an IC_{50} of $44.834 \mu\text{g/ml}$ and a higher anticancer activity compared to DOX ($\text{IC}_{50} = 46.82 \mu\text{g/ml}$). PG-AgNPs proved to be efficient, and as their anticancer efficacy increased with increasing concentration (Table 1).

In silico study

The *in silico* investigation for MEK1 kinase of the docked poses was performed on the basis of MolDock score followed by Rerank score and hydrogen bond interaction (H-bond) score. The best docking score for MEK1 kinase of the MolDock score was -162.59 with -130.103 Reranking score (Table 2). The binding affi-

nity of selected inhibitors at the active site of human MEK1 kinase using MVD in decreasing order was PG-AgNPs (-162.59), prodigiosin (-144.707), and DOX (-74.7941), respectively, based on MolDock and Rerank scores. Figure 14 shows the predicted active site in the human MEK1 kinase protein (4LMN) with the cavity marked with a green mesh. The best docking score to the receptor and the highest affinity of binding were recorded for PG-AgNPs (-163.342) followed by prodigiosin (-145.714) and DOX (-87.6882) (Table 3). DOX, although having a low Rerank score, showed a good stability by the formation of four hydrogen bonds in the same cavity (Fig. 15). The prodigiosin docking hits showed common molecular interaction with Serine 212 (Ser 212). The ligand-protein interaction and the binding mode for top three docking hits are shown in Table 2 and Figure 15.

Table 2. The comparative docking simulation results of selected prodigiosin-conjugated AgNPs, prodigiosin and doxorubicin with human MEK1 kinase including interacting residues and number of H-bonds, ligand from X-ray crystallized data of the protein data bank (4LMN.pdb) using MVD

Ligand	MolDock score	Rerank score	HBond	MW	Docking score	Interacting residues of receptor human MEK1 kinase	Number of H-bonds
Prodigiosin-conjugated nanosilver	-162.59	-130.103	-3.81776	446.291	-163.342	Val211, Ser 212	2
Prodigiosin	-144.707	-118.643	0	323.432	-145.714	Ser 212	1
Doxorubicin	-74.7941	-71.7672	-9.19366	534.448	-87.6882	Lys 192, Ile 216, Met 219, and Asn 221	4

Discussion

Nanoparticles have opened a new area in the field of cancer therapy because of their unique properties such as small size, controlled release of drugs, and reduced toxic side-effects. Prodigiosin pigment has antifungal, antibacterial, antiprotozoal, antimalarial, cytotoxic, and immunosuppressive activities (Samrot et al., 2011). The present study focused on the synthesis of AgNPs using prodigiosin produced by *Serratia marcescens* isolate WSE. Only a few research attempts focus on an *in vivo* setting to establish prodigiosin or prodigiosin derivatives-based antimicrobial agents, drug toxicity, and antitumor agents by using them in a combination with nanometals.

AgNPs exhibit a yellowish-brown color in aqueous solutions. Changes in the color of the reaction mixtures from red to brown are due to the excitation of SPR of AgNPs with its characteristic absorbance at 439 nm (Fig. 14) (Kreibig and Vollmer, 1995; Mulvaney, 1996;

Shankar et al., 2004; Xia and Halas, 2011; Muthukrishnan and Nanda, 2013). The absorption peak assigned to the SPR band of AgNPs, can be attributed to the collective oscillation of the conduction electrons of metallic nanostructures induced by the incident light field (Guo et al., 2014). The intensity and width of the SPR depend on size, shape, morphology, spatial orientation, optical constants of the particles and the surrounding environment (Mulvaney, 1996; Knoll and Keilmann, 1999; Huang and Xu, 2010).

The alkaline pH plays an important role in the synthesis of smaller size AgNPs, where a broad peak related to AgNPs synthesis starts appearing at pH 9. The intensity of the band increased as the pH value increased, and as the size of AgNPs formed reduced. In addition, due to an increase in the Ag⁺ ion reduction rate, the AgNPs synthesis rate increased with increasing pH (Abdel-Mohsen et al., 2014). The alkaline conditions accelerated AgNO₃ reduction rate. However, at acidic or

neutral pH no reduction was observed. Under the alkaline conditions, the absorption peak of AgNPs showed high intensity and blue shift as an indication that the concentration of AgNPs increased and the size was reduced, respectively. As the pH value reduced, the surface plasmon band of the AgNPs red-shifted toward longer wavelengths which indicated that the size of AgNPs

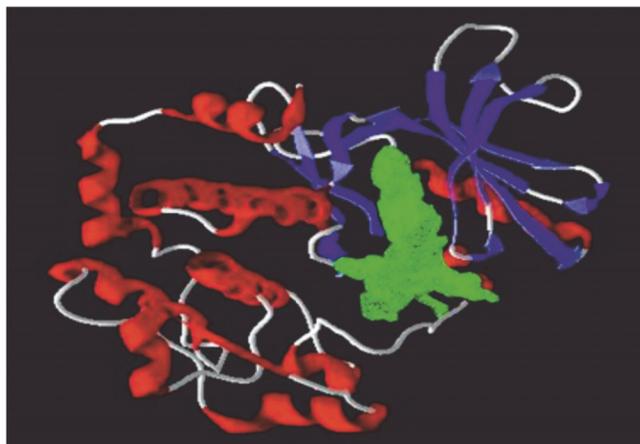

Fig. 14. Human MEK1 kinase protein (4LMN) showing the cavity (green mesh) at the active site

could be controlled by varying the pH from 9 to 13 (Kerker, 1985; Sönnichsen et al., 2002; Ganesh Babu and Gunasekaran, 2009; Abdel-Mohsen et al., 2014). The temperature of the synthesis reaction of AgNPs influences AgNPs growth, shape, and size. The results of our experiments suggest that silver ion reduction strongly depended on the reaction temperature, i.e., at higher reaction temperatures the reduction rate of silver ions (Ag^+) to AgNPs (Ag^0) increased (Abdel-Mohsen et al., 2014). Lower reaction temperatures usually resulted in formation of AgNPs with a narrower size distribution. The control of uniform shape is a very important step for the efficient utilization of temperature in the synthesis of AgNPs using prodigiosin. It is well known that an absorption band appears at 419-475 nm in a 10-100 °C temperature range and is related to SPR of AgNPs (Aslan et al., 2005; Abdel-Mohsen et al., 2012; Hyllested et al., 2015). When the temperature was increased to 30 °C, the mean size of AgNPs increased to 11.25 nm. A further increase in the temperature (to 70 °C) resulted in well-dispersed, uniform sized AgNPs of about 51.22 nm; however, an increase to 100 °C resulted in the formation of smaller, uniformly sized AgNPs of about 34.75 nm.

It is easily understandable that AgNO_3 concentration plays a role in size and shape of formed nanoparticles. It has been shown that due to its role in increasing the reduction rate the peak intensity increased as the AgNO_3 concentration increased from 1 to 10 mM (Dubey et al., 2010; Zaki et al., 2012; Maria et al., 2014). The SPR band red-shifted with the increasing concentration of AgNO_3 from 1 mM to 10 mM indicating an increase in the size of AgNPs. It can therefore be assumed that the maximum absorbance peak will red-shift to longer wavelengths when the particle size increases (Heard et al., 1983; Abdel-Mohsen et al., 2014). This result showed that the increase in silver ion concentration induced the growth of AgNPs and resulted in increased particle size (Jiang et al., 2008). The appearance of a peak at 417 nm in a SPR indicated the formation of AgNPs (Wang et al., 2004). The maximum absorbance peak intensity increased gradually with the increase in the AgNO_3 concentration until 3 mM AgNO_3 . At a concentration of 4 mM AgNO_3 another phenomenon, formation of anisotropic rod-shaped AgNPs, was observed that were confirmed using TEM and DLS (Annadhasan et al., 2014). The shape of AgNPs changed from spherical to anisotropic nano-rod structures, when AgNO_3 concentration increased to 4 mM and at prodigiosin concentration of 4 $\mu\text{g}/\text{ml}$. The formation of nanoparticles could be observed when prodigiosin concentration was within a suitable range for nucleation. The results indicated that using 4 $\mu\text{g}/\text{ml}$ prodigiosin was sufficient for the synthesis of well-defined AgNPs. No AgNPs were observed below that concentration. The characteristic SPR band of the solution was observed between 420-425 nm at a concentration of prodigiosin higher than 2 $\mu\text{g}/\text{ml}$, which could be due to the formation of spherical-shaped AgNPs (Annadhasan et al., 2014). It is well known that a surface plasmon band of spherical AgNPs appears around 420 nm (Park et al., 2003; Suber et al., 2005; Chang et al., 2014). The particle size obtained from DLS measurement was larger than TEM result (9.98 nm), because DLS measures the hydrodynamic radius that considers the prodigiosin pigment on the surface of AgNPs (El-Batal et al., 2014). Spherical-shaped nanoparticles with a mean diameter of 14.86 nm were obtained at pH 13 after 18 h of reaction with 500 $\mu\text{g}/\text{ml}$ prodigiosin at 1 mM of AgNO_3 (Sönnichsen et al., 2002). The synthesis of AgNPs using prodigiosin was also confirmed by characteristic peaks observed by XRD. The major peaks at 2θ of about 38.1°, 44.3°, 51.8°, 56.3°, 60.8°, 65.3°, 69.8°, 74.3°, 78.8°, 83.3°, 87.8°, 92.3°, 96.8°, 101.3°, 105.8°, 110.3°, 114.8°, 119.3°, 123.8°, 128.3°, 132.8°, 137.3°, Fig. 15. Comparison of the docking interaction: 1A and 1B – for prodigiosin-conjugated nanosilver, 2A and 2B – for prodigiosin, and 3A and 3B – for doxorubicin with human MEK1 kinase (4LMN)

64.5°, 77.5°, and 81.5° of AgNPs were assigned to the (111), (200), (220), (311), and (222) crystallographic planes [JCPDS card No. 01-1167] for silver nanocrystals, respectively (Hanawalt et al., 1938; Das et al., 2011). The highly intense diffraction peak observed at 38.1° confirmed a formation of pure crystalline AgNPs (Das et al., 2011; El Baz et al., 2015). The reduction and stabilization mechanisms involved in the synthesis of AgNPs were investigated using FTIR. The efficient conjugation of prodigiosin to form AgNPs and possible functional groups of capping agents were achieved through the chemical reaction of negatively charged silver oxide (AgO^-) and positively charged nitrogen atom of pyrrole ring. The reaction resulted in the formation of prodigiosin silver oxide, as confirmed by FTIR spectra. The FTIR spectra revealed that four bands between 400-4000 cm^{-1} wavenumbers (at 2815.2 cm^{-1} , 1654.0 cm^{-1} , 1438.0 cm^{-1} , and 1423.0 cm^{-1}) showed significant changes after the reduction of silver ions and formation of PG-AgNPs.

Some members of prodigiosin family have great potential of inducing apoptosis in various human hematopoietic cancer cells, colon cancer cells, B-cell, and chronic lymphocytic leukemia cells. Interestingly, prodigiosin does not have any marked toxicity in nonmalignant cell

lines (Campàs et al., 2003; Kavitha et al., 2010). Apoptosis in liver cancer (HepG2) cells and cytotoxic mechanism induced by functionalized gold nanoparticles were studied and evaluated using 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide MTT ((4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide) assay and sulforodamine B (SRB) assay, Annexin-V/PI double-staining assay, cell cycle as reported by Ashokkumar and co-workers (2014).

DOX is one of the most widely used chemotherapeutics for the treatment of hepatocellular cancer. It is also an anticancer drug that induces apoptosis and chemosensitivity in hepatoma cell lines, human hepatocellular cancer cell lines (HepG2), which were targeted with DOX and MEK enzyme inhibitors, alone or in combination (Friedman, 1983; Chlebowski et al., 1984; Lai et al., 1988; Lin et al., 1997; Yang et al., 2000; Lee et al., 2002; Xu et al., 2011). HepG2 cell line is widely used for *in vitro* studies. It mostly expresses drug-metabolizing enzymes, and is also widely used as a cellular experimental model in pharmaceutical studies for the production of new drugs and to gain insights into drug metabolism, including enzymes drug's inhibition or induction potential (Knasmüller et al., 1998; Castell et al., 2006; Qiu et al., 2015).

Hassankhani and coworkers (2015) reported that prodigiosin may have a great potential for colorectal cancer-directed therapy as it induced apoptosis in HT-29 cells (Hassankhani et al., 2015). The toxicity potential of prodigiosin and PG-AgNPs on liver cancer cells was examined using the HepG2 cell line. The cells were exposed to various concentrations of prodigiosin and PG-AgNPs for 24 h and 48 h, and the toxicity effects were assessed after that period. The results showed that PG-AgNPs decreased cell viability in a time-dependent manner. In the present study, the effects of DOX, PG-AgNPs, and prodigiosin, on liver cancer cells, both *in vitro* and *in silico*, were examined. The cytotoxicity assessment is essential to any study of therapeutic potential of various compounds, particularly when assessing their applicability as an anti-cancer drug. The inhibitory concentration (IC₅₀ value) for PG-AgNPs was determined to be 29.8548 µg/ml, however, the inhibitory concentration of prodigiosin (IC₅₀ value) was 44.834 µg/ml. The lower the value of the half maximal inhibitory concentration (IC₅₀) of a drug, the higher is the sensitivity to the drug treatment. MEK inhibition may hold promise for the treatment of hepatocellular cancer and potential for treatment of some cancers (Wang et al., 2007; Choi et al., 2008; Hatzivassiliou et al., 2013). Choi and coworkers (2008) analyzed DOX combined with mitogen-activated protein kinase-extracellular signal-regulated kinase (MEKERK)-targeted therapy and suggested that the treatment begins from the time of DOX addition which may provide enhanced anticancer effects (Choi et al., 2008). The *in silico* study showed a higher affinity between PG-AgNPs and human MEK1 kinase than with prodigiosin and DOX, which was confirmed by the Rerank score. The interaction was analyzed by the formation of the hydrogen bond with human MEK1 kinase, where it was observed that PG-AgNPs formed two hydrogen bonds with Val211 and Ser 212 in the active site cavity. The hydrogen bonds between prodigiosin and Ser 212 were formed with human MEK1 kinase active site. Interestingly, four hydrogen bonds were formed between DOX and Lys 192, Ile 216, Met 219, and Asn 221.

Conclusions

Different shapes and sizes of nanoparticles can be synthesized by controlling the reaction conditions. Prodigiosin pigment has a promising role in stabilization and synthesis of AgNPs as a reducing and capping agent.

In the present *in vitro* and *in silico* analyzes a high therapeutic potential of PG-AgNPs against human liver cancer and MEK1 kinase inhibition is shown. The present investigation demonstrated the potential of prodigiosin conjugated with AgNPs for apoptosis studies in liver cancer cells.

Acknowledgments

The authors would like to thank the Nanotechnology Research Unit (P.I. Prof. Dr. Ahmed Ibrahim El-Batal), Drug Microbiology Lab, Drug Radiation Research Department, NCRRT, Cairo, Egypt, for financing and supporting this study under the project *Nutraceuticals and Functional Foods Production by using Nano/Biotechnological and Irradiation Processes*.

Author contribution

All authors conceived the study, wrote the manuscript, designed and performed the experiments, analyzed and interpreted data, supervised the research, and interpreted data. Also, all authors read, revised, and approved the final manuscript.

Compliance with ethical standards

Conflict of interest

The authors declare that they have no conflict of interest.

Ethical statement

This article does not contain any studies with human participants or animals performed by any of the authors.
