Loiseleuria procumbens (Ericaceae) in the Ukrainian Carpathians

Abstract: Distribution of *Loiseleuria procumbens* (L.) Desv. in the Eastern Carpathians of Ukraine is presented on the basis of herbaria, literature and the authors' field studies. Site conditions of species occurrence and its phytocoenotic properties are described. The needs' of protection of *L. procumbens* and its plant communities are discussed.

Additional key words: plant geography, chorology, ecology, phytocoenology, plant protection

Introduction

The alpine azalea (*Loiseleuria procumbens* (L.) Desv.) very rarely occurs in Ukraine, and only in the Carpathians. The authors had an opportunity to find this species in several locations in the Charnokhora Mts in 1997–1999. The field observations and studies allow us to compare the site conditions of *L. procumbens* with those of other plants typical for the subalpine/alpine belt of the Eastern Carpathians of Ukraine (Didukh and Boratyński 2000). The aim of the present study is to show actual distribution of *L. procumbens* in Ukraine, describe the local site conditions of the species here and determine its phytocoenotic character.

General distribution

Loiseleuria procumbens belongs to species with amphi-Atlantic type of range, but it can be also regarded as circumpolar with a large gap in North-West

Asia (Hultén, Fries 1986). It occurs mainly in the arctic and subarctic zones of Europe, Asia and North America, also in the high mountain massifs of temperate regions of these continents (Hultén 1968; Meusel et al. 1978, Hultén, Fries 1986). In northern Europe the species grows southwards to 58° N latitude on the Scandinavian Peninsula (Hultén 1971) and to 56° in Scotland (Perring, Walters 1962). In addition to the range of distribution on the North, the alpine azalea occurs in the high mountains of central Europe (Fig. 1). It is even locally common in the alpine/subalpine layers of the Alps and Pyrenees and grows sparsely in the Carpathians (Fig. 2). The species presents an arctic-alpine type of range in Europe.

The most elevated European localities of *L. procumbens* have been reported from altitudes of 3100 m in the Alps of France and 2900 m in Switzerland (Braun-Blanquet and Rübel 1934; Meusel et al. 1978). The species attains 2600 (2850) m in the Pyrenees (Villar 1993), and about 2100 m in the Carpathians (*in sched.*).

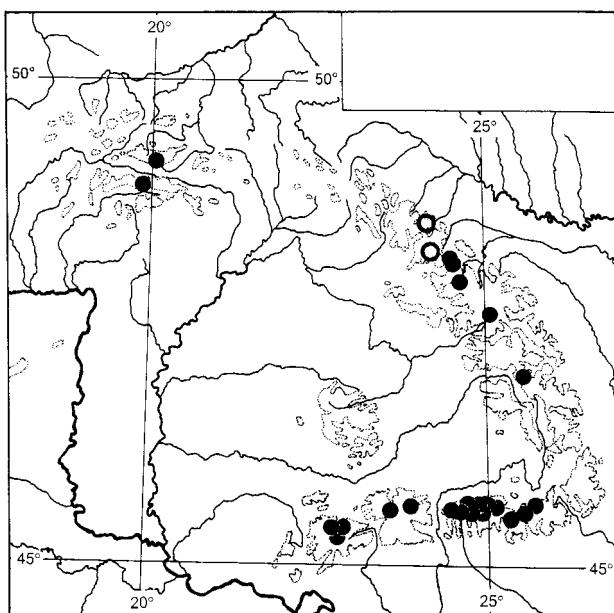

Fig. 2. Distribution of *Loiseleuria procumbens* in the Carpathians (on the basis of data of Țopa 1960; Jasičová 1982, supplemented)

Occurrence in the Ukrainian Carpathians

Loiseleuria procumbens is a well defined species without taxonomic problems, however, individual specimens of the species have been found erroneously determined among the materials of *Empetrum nigrum* L. and *E. hermaphroditum* Hagerup in several herbaria

studied. Available herbarium materials, literature data and our own field observations allow us to draw a distribution map of *L. procumbens* and to give some ecological comments concerning conditions of occurrence of the species in the Ukrainian Carpathians.

Data on the occurrence of *Loiseleuria procumbens* in the Ukrainian Carpathians were reported several times (Jávorka 1924; Wilczyński 1931; Pawłowski 1937; Barbarich 1957; Kotov and Chopik 1976; Chopik 1976; Malinovsky 1980; Barbarich 1987). Most of species locations were reported from the Charnokhora main range, with single, isolated locality on Mt. Petros, as it was shown on a map published recently by Malinovsky (1998), and another single locality on the Kostrich Mt (Swiderski and Szafran 1931). The other data reporting the occurrence of *L. procumbens* in the Ukrainian Carpathians (Fig. 3) concern the Svidovec and the Gorgany ridges. From the former only one mention could be found: ridge of Swidovec (Domin, after Barbarich 1957), with no subsequent confirmation. Reviewing herbaria we have also encountered specimens of *L. procumbens* collected from Sywula, Ihrovishche and Matakhov in the Gorgany Mts (szczyty Matachów, Ihrowiszcze, Siwula na granicy Węgierskiej Stryjskiego powiatu, lg. Zipser, 1865, KRAM¹, 170827). Occurrence of the species in this mountain range has also never been confirmed.

The Alpine azalea is a characteristic species of alpine-subalpine belt in the Charnokhora Mts and most of its localities were reported from altitudes between 1550 m on the north-eastern slopes of Khoverla and 2000 m on the tops of Rebra, Pohyhzevska and Pop Ivan Mts (Fig. 4). No occurrence has been found below the upper forest line (compare: Środoń 1948). The alpine-subalpine character of the species in the

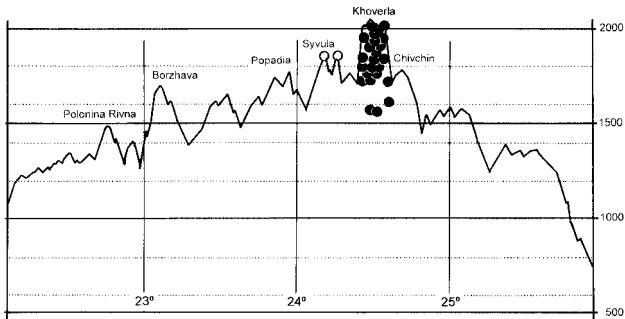

Fig. 4. Vertical distribution of *Loiseleuria procumbens* localities in the Ukrainian Carpathians

Charnokhora is also demonstrated in exposition of its localities. The authors' field observations, data gathered from the herbaria labels and from phytosociological inventories allow us to state, that most locations of *L. procumbens* are N- or NE-facing (Fig. 5).

Ecological and phytocoenotical character of the species

Loiseleuria procumbens grows in the Charnokhora Mts on the open places, mostly on the rocks or on the slopes with rather shallow stratum of soil, exclusively derived from siliceous rocks. The humus stratum, however, can be deeper below procumbent branches of the species, than in other plant communities in the alpine belt of the mountains. The humus is protected against the wind erosion and can accumulate, similar as inside the cushion-like specimens of other species, which occur in the Arctic and Alpine zones.

Loiseleuria procumbens frequently forms its own associations in the Charnokhora Mts. These communities are most often developed at the altitudes between 1750 and 2000 m, on weakly inclined slopes or on fairly convex, small, North-facing, lateral ridges of the main range of Khovala – Pop Ivan. The largest areas

of the species communities are found between mountains Gutin-Tomnatek and Brebenieska (Malinovsky 1980, 1998), on the places characterized with strong snow drifting processes causing reduced snow cover in the winter. On the open, upper parts of the slopes, especially where the terrain is somewhat convex, the snow is blown away and plants are exposed to the frost and wind action. These site conditions have the most continental character among all parts of alpine zone of Eastern Carpathians. It is probably connected with low height of the species, which allow it to take advantage of retain heat reflected off surface even at low temperatures (Grace et all. 1989). In comparison *L. procumbens* forms its communities in the snow-bed site conditions in the arctic (Razzhivin 1994).

Geobotanical characteristics of *Leuseleuria procumbens* communities in the Charnokhora Mts have been described several times on the basis of dominant species composition (Malinovsky, Berezhnoy 1956, Golubec, Malinovsky 1969, Kemendar 1969, Malinovsky 1980, Stoyko 1987, Tasenkevich 1998). The specific associations formed by the species were considered as formation *Loiseleurietalia procumbentis*, in which, depending on species coexisting with *L. procumbens*, 3 associations were described – *Loiseleurietum (procumbentis) purum* (= *Loiseleurietum petraeum*), *Loiseleuria procumbens+Cetraria islandica* and *Loiseleuria procumbens+Carex curvula* (Malinovsky 1980, Stoyko 1987).

Syntaxonomic position of *L. procumbens* communities from Charnokhora was recently studied using the Braun-Blanquet methodology (Kricsfalushy et all. 1991; Malinovsky, Kricsfalushy 2000). The species occurs exclusively in the plant communities from Class *Loiseleurio-Vaccinietales* Eggler ex Schubert 1960 and Ordo *Rhododendro-Vaccinietales* Br.-Bl. in Br.-Bl. et Jenny 1926, and most abundantly in associations from alliance *Loiseleurio-Vaccinion* Br.-Bl. in Br.-Bl. et Jenny 1926 (Malinovsky, Kricsfalushy 2000). In this alliance it forms the association *Loiseleurio-Cetrarietum* Br.-Bl. et al. 1939, where it is a dominant species. It also enters other associations from this alliance, as *Empetrio-Vaccinietum gaultherioides* Br.-Bl. in Br.-Bl. et Jenny 1926 corr. Grabherr 1993 and *Cetrario-Vaccinietum gaultherioides* Hadaè 1956. *L. procumbens* can be also found sporadically in the association *Rhododendretum myrtifolii* Puscaru et al. 1956 from *Rhododendro-Vaccinion* Br.-Bl. 1926 alliance (Malinovsky, Kricsfalushy 2000).

The association of *Loiseleurio-Cetrarietum* and most of other plant communities with participation of *Loiseleuria procumbens* can be easily distinguished in the field by its specific physiognomy. They are dominated by small, more or less prostrate shrubs. The diagnostic plants of *Loiseleurio-Cetrarietum* in the Charnokhora (participation above II degree) are *L. procumbens*, *Vaccinium gaultherioides* Bigelow², *Carex curvula* All.,

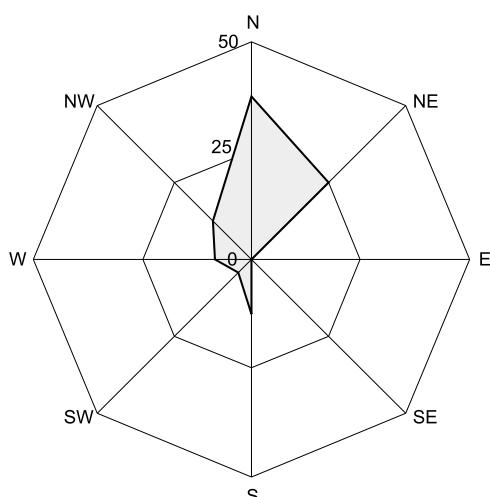

Fig. 5. Exposition of *Loiseleuria procumbens* localities in the Charnokhora range

Juncus trifidus L., *Doronicum clusii* (All.) Tausch, *Homogyne alpina* (L.) Cass., *Soldanella hungarica* Simonk., *Pulsatilla scherfelii* (Ullep.) Skálický, *Primula minima* L., *Campanula alpina* Jacq. and *Hieracium alpinum* L. From the surrounding communities frequently enter such species as *Empetrum hermaphroditum* Hagerup, *Rhododendron myrtifolium* Schott et Kotschy, *Vaccinium vitis-idaea* L., *V. myrtillus* L. and other. Most of the vascular plant species coexisting with *Loiseleuria procumbens* in its specific communities belong to the arctic-alpine or alpine elements.

The community of *Loiseleurio-Cetrarietum* is abundant in moss and lichen species. To the former belongs the common species, which occur in many plant communities, as *Racomitrium lanuginosum* (Hedw.) Brid., *Polytrichum piliferum* Hedw. and *Dicranum scoparium* Hedw. The most important lichen species are *Cetraria islandica* (L.) Ach., *Cladina rangiferina* (L.) Nyl., *Alectoria ochroleuca* (Hoffm.) Massal., *Thamnolia vernicularis* (Schwartz) Scher. and *Cladonia macroceras* (Delise) Haw. (Malinowsky, Kricsfalushi 2000).

The floristic composition of associations with *Loiseleuria procumbens* in the Charnokhora Mts does not differ strongly from those described in other mountain ranges of the Carpathians (Topa 1960; Coldea 1991).

Protection

The species *Loiseleuria procumbens*, as well as communities which it forms, particularly *Loiseleurio-Cetrarietum*, are very rare in the Ukrainian Carpathians. For this reason the species and associations with its participation deserve to be protected. The need to protect *Loiseleuria procumbens* and associations in which it occurs have been mentioned several times (Wilczyński 1931; Klaštersky 1935; Pawłowski 1937; Malinovsky, Berezhny 1956; Komendar 1969; Kotov, Chopik 1976; Stoyko et all. 1982; Shelyag-Sosonko et all. 1987; Kricsfalushiy et all. 1991; Kricsfalushiy, Malinovsky 1993; Tasenkevich 1998). The best way to conserve plant associations containing *L. procumbens* in the Charnokhora Mts will be exclusion from intensive pasturing areas, where they are formed. Pasture lands in the Charnokhora Mts were traditionally burned by pastors (Vincenz 1936). This kind of treatment is very damaging to *L. procumbens* specimens and was recognized as the main threat (Komendar 1969). However, moderate browsing and reduction of thicket of *Pinus mugo* and *Juniperus communis* subsp. *alpina* should be recommended to prevent specimens of *L. procumbens* from being shaded. This latter recommendation applies to the lowest locations of the species, where it forms small clumps on rocky places among *Pinus mugo* thick-

ets, as on the Smotrich slopes above Dzhembonia, and even in the *Pinus cembra* forest, as for example on the Gadzhyna Mt. in the place named Mreye (Wilczyński 1931).
