Sammury. To assess effect of production process for standardized properties the samples were taken-off from the six referential decentralized and one industrial production plants for rapeseed oils. Their properties limited by technical standard for rapeseed oils as a fuel were determined in laboratory. Further the long-term investigation of oxidation stability change was started in storage trial of rapeseed oils with additive of 200, 400 and 600 ppm of antioxidant Baynox. The results have shown that critical points of that process of rapeseed oils acquisition are contamination by the ash-producing elements, i.e. phosphorus, magnesium, calcium and total pollution. Not only in hot pressing but also in the double-stage cold pressing of rapeseed it is necessary reduction of the ash-producing elements through other technological operations as degumming, neutralization, bleaching. It is always necessary to provide security stage of filtration before distribution for maximum particles size of 1 μm . It had been proved the unambiguously positive effect of the antioxidation additive Baynox, when 200 ppm addition caused increasing of the oxidation stability of rapeseed oil grown at least 6 hours immediately after pressing from 8 hours to 9.05 hours and after 270 days it decreased to 6 hours. The monitoring brought the necessary knowledge for the process of the rapeseed oils acquisition optimization and their distribution for motor application. The monitoring also is a basis for establishing of necessary controlling of the rapeseed oils production quality.

Key words: technical standard, rapeseed oil, fuel.

INTRODUCTION

The number of decentral oil mills is increasing rapidly. The rapeseed oil can be also utilized as a fuel for modified diesel engines. For a reliable operation of adapted diesel engines, the rapeseed oil fuel has to fulfil special quality requirements, which are defined in the technical standard [1, 2, 3, 4]. It was the purpose of this work to investigate influences of the whole production process on rapeseed oil fuel properties. To survey the rapeseed oil quality, available on the market, oil samples

were periodically taken from several oil mills and analysed.

OBJECTS AND METHODS

In order to determine and compare the quality of rapeseed oils, there were taken out the testing batches from six decentralized production units and one industrial oil plant (see Table 1). The subsequent analyses of testing samples have been carried out by the method enabling the comparison with specification of required limit values of technical standard ČSN

65 6516 „Fuels for vegetable oil compatible oil“ [5].

RESULTS AND DISCUSSION

The measured characteristics have shown the great difference in quality of testing samples (see Fig. 1 – 8). In all manufacturing plants there was processed rapeseed, which fulfilled the qualitative purchase conditions. It helped as well to ensure in decisive extent the meeting of demands for water content, acidity number and oxidative stability in assessed oil plants. However, to the critical points in the process of rapeseed oil obtaining, belong the contamination by phosphorus, metals of second

group (magnesium and calcium) and total content of contamination from rapeseed solid residues. The consequential detailed investigation of reasons of this state enabled to determine the factors, which caused this contamination. Therefore, it is possible to state as follows:

- Behind the one-stage cold pressing of rapeseed, which decreased the level of contamination caused by phosphorus, magnesium and calcium under limit values of technical standard ČSN 65 6516 [5], it is necessary to place the second safety degree of

filtration with filtration ability of particles in line filter max. 1 μm .

- The two-stage cold pressing and also hot pressing, resp. industrial processing with extraction, is always connected with content of phosphorus and very often also magnesium and calcium in rapeseed oil over limit values. Therefore, it must always follow the removal of mucus, eventually neutralization or other operations, e.g. whitening or filtration through hydrophobic membranes, which however lead to cost increase and that's why it is necessary to select them carefully. In respect to removal of mucus, besides of conventional procedures, it is possible to recommend so-called „superdegumming“. Before, there are combined the acid and water and thereby comes not only to high grade of phospholipide separation, but also to considerably lesser occurrence of water. It can be applied Total Degumming Process, which can be used not only for raw oils, but also for oils with mucus removed by water and it is based, in principle, on addition of acid and lye

with consecutive separation. During this process the phospholipides are almost completely taken away. It is also possible to use the enzymatic process for removal of mucus „EnzyMax Degumming“.

Oxidation stability is other important indicator determining suitability of rapeseed oil utilization as a fuel from the storage point of view and with it related degradation. The continuous of rapeseed oils storage test with preparation Baynox 200, 400 a 600 ppm in PVC vessels with access of air and stored in unheated room illuminated only by daily light in the course of 420 days is shown on fig. 9.

Monitoring brought the essential evidences and knowledge for optimalization of rapeseed oils obtaining and their distribution as the motor fuels. It forms also the starting basis for creation of necessary quality assessment. Its implementation into practice represents necessary condition for maintenance of stable and high quality of motor fuel manufactured from the rapeseed oil.

CONCLUSIONS

To assess effect of production process for standardized properties the samples were taken-off from the six referential decentralized and one industrial production plants for rapeseed oils. Their properties limited by technical standard for rapeseed oils as a fuel were determined in laboratory. Further the long-term investigation of oxidation stability change was started in storage trial of rapeseed oils with additive of 200, 400 and 600 ppm of antioxidant Baynox. The results have shown that critical points of that process of rapeseed oils acquisition are contamination by the ash-producing elements, i.e. phosphorus, magnesium, calcium and total pollution. Not only in hot pressing but also in the double-stage cold pressing of rapeseed it is necessary reduction of the ash-producing elements through other technological operations as degumming, neutralization, bleaching. It had been proved the unambiguously positive effect of the antioxidation additive Baynox, when 200 ppm addition caused increasing of the oxidation stability of rapeseed oil grown at least 6 hours immediately after pressing from 8 hours to 9.05 hours and not until after 270 days decreased under limit value 6 hours. With using of addition 400 ppm Baynox decreased oxidation stability under 6 hours not until after 390 days of storage. With addition 600 ppm Baynox the oxidation stability of rapeseed oil even after 510 days of storage makes 6.5 hours. The monitoring brought the necessary knowledge for the process of the rapeseed oils acquisition optimization and their distribution for motor application. The monitoring also is a basis for establishing of necessary controlling of the rapeseed oils production quality.

The work comprises partial results of the research project of the Ministry of Agriculture of the Czech Republic 0002703102 – Part 5: Technological processes of sustainable production and utilization of bio-raw materials and energy carrier of new generation with

respect to food security and global market with relevant products.
